

## Assessment Schedule – 2025

### Chemistry: Demonstrate understanding of equilibrium principles in aqueous systems (91392)

#### Evidence Statement

Q	Evidence	Achievement	Achievement with Merit	Achievement with Excellence
ONE (a)(i)	$\text{Fe}(\text{OH})_2(\text{s}) \rightleftharpoons \text{Fe}^{2+}(\text{aq}) + 2\text{OH}^{-}(\text{aq})$	<ul style="list-style-type: none"> <li>Correct equation and <math>K_s</math> expression.</li> </ul>		
(ii)	$K_s = [\text{Fe}^{2+}][\text{OH}^{-}]^2$			
(iii)	$K_s = (1.01 \times 10^{-5}) \times (2 \times 1.01 \times 10^{-5})^2$ $K_s = 4.12 \times 10^{-15}$	<ul style="list-style-type: none"> <li>Method correct for determining <math>K_s</math>.</li> </ul>	<ul style="list-style-type: none"> <li>Correct <math>K_s</math>, including 2–4 significant figures.</li> </ul>	
(iv)	<p>When HCl is added, the <math>[\text{H}_3\text{O}^+]</math> increases. The <math>\text{H}_3\text{O}^+</math> react with the <math>\text{OH}^-</math> (in an acid-base reaction). The equation for this reaction is:</p> $\text{H}_3\text{O}^+(\text{aq}) + \text{OH}^{-}(\text{aq}) \rightarrow 2\text{H}_2\text{O}(\ell)$ <p>This decreases <math>[\text{OH}^-]</math> in the system, so the rate of the forward reaction increases to replace the <math>\text{OH}^-</math> ions. This causes more <math>\text{Fe}(\text{OH})_2(\text{s})</math> to dissolve and hence <math>\text{Fe}(\text{OH})_2</math> becomes more soluble.</p>	<ul style="list-style-type: none"> <li>Recognises <math>[\text{H}_3\text{O}^+]</math> increases.</li> </ul>	<ul style="list-style-type: none"> <li>Explains that a decrease in <math>[\text{OH}^-]</math> due to reaction with <math>\text{H}_3\text{O}^+</math> will favour formation of more <math>\text{OH}^-</math> in solution / favour forward reaction.</li> </ul>	<ul style="list-style-type: none"> <li>Justifies what will happen to the solubility of <math>\text{Fe}(\text{OH})_2</math> when HCl is added, including relevant balanced equation.</li> </ul> <p>AND</p>
(b)(i)	<p>When NaCN is added, the <math>\text{Ni}^{2+}</math> ions form a complex with the added <math>\text{CN}^-</math> ions:</p> $\text{Ni}^{2+}(\text{aq}) + 4\text{CN}^{-}(\text{aq}) \rightarrow [\text{Ni}(\text{CN})_4]^{2-}(\text{aq})$ <p>This decreases <math>[\text{Ni}^{2+}]</math> in the system, so the rate of the <math>\text{Ni}(\text{OH})_2</math> dissolving reaction increases to replace the <math>\text{Ni}^{2+}</math> ions. This causes the precipitate to dissolve/solubility increases. Because an excess of cyanide ions is added and the complex ion is water soluble, eventually all of the <math>\text{Ni}(\text{OH})_2</math> dissolves.</p>	<ul style="list-style-type: none"> <li>Recognises the <math>\text{Ni}(\text{OH})_2</math> precipitate dissolves due to formation of a complex ion.</li> </ul>	<ul style="list-style-type: none"> <li>Explains that the formation of the complex ion causes a decrease in <math>[\text{Ni}^{2+}]</math>.</li> </ul>	<p>Explains that the formation of the complex ion causes the rate of the forward / dissolving reaction to increase to replace the <math>\text{Ni}^{2+}</math>, including the balanced equation to show complex ion formation.</p>

(ii)	$[\text{Ni}^{2+}] \text{ in mixture} = \frac{0.130 \times 55.0}{90.0}$ $= 0.0794 \text{ mol L}^{-1}$ $[\text{OH}^-] \text{ in mixture} = \frac{1 \times 10^{-14}}{10^{-11.7}} \times \frac{35.0}{90.0}$ $= 1.95 \times 10^{-3} \text{ mol L}^{-1}$ <p>In the mixture: <math>\text{IP} = [\text{Ni}^{2+}][\text{OH}^-]^2</math></p> $= 0.0794 \times (1.95 \times 10^{-3})^2$ $= 3.02 \times 10^{-7}$ <p>Since <math>\text{IP} &gt; K_s</math>, a precipitate forms.</p>	<ul style="list-style-type: none"> <li>• Calculates <math>[\text{Ni}^{2+}]</math> or <math>[\text{OH}^-]</math>.</li> <li>• Correctly compares IP and <math>K_s</math>.</li> </ul>	<ul style="list-style-type: none"> <li>• Correct process to calculate IP and compare with <math>K_s</math>, but one of the solutions is not appropriately diluted. e.g. <math>[\text{OH}^-]</math> given as <math>5.01 \times 10^{-3}</math> (IP is <math>1.99 \times 10^{-6}</math>).</li> </ul> <p>Cannot multiply <math>[\text{OH}^-]</math> by 2.</p>	<ul style="list-style-type: none"> <li>• Correct calculation and comparison, including 2–4 significant figures.</li> </ul>

Q	Evidence	Achievement	Achievement with Merit	Achievement with Excellence
TWO (a)	$\text{Cl}^-$ , $\text{CH}_3\text{NH}_2$ , $\text{OH}^-$	<ul style="list-style-type: none"> <li>All correct.</li> </ul>		
(b)(i)	A buffer solution resists a change in pH / maintains a fairly constant pH when a small volume of either strong acid or strong base is added. When NaOH is added, the $\text{CH}_3\text{NH}_3^+$ ions react with (neutralise) the $\text{OH}^-$ to form the weaker base, $\text{CH}_3\text{NH}_2$ . As a result, the pH does not change significantly.	<ul style="list-style-type: none"> <li>Correct description of the function of a buffer solution.</li> </ul>	<ul style="list-style-type: none"> <li>Explains how the buffer resists a change in pH when NaOH is added and that the <math>\text{CH}_3\text{NH}_3^+</math> ions / acidic component of buffer neutralise / react with / remove the added <math>\text{OH}^-</math> ions.</li> </ul>	<ul style="list-style-type: none"> <li>Correctly calculates the mass of <math>\text{CH}_3\text{NH}_3\text{Cl}</math>, including unit and 2–4 significant figures.</li> </ul> <p>AND</p> <p>Explains why the solution cannot function as a buffer and outlines how the solution needs to be modified for use as a buffer solution by adding a strong acid / <math>\text{HCl}</math> / <math>\text{H}_2\text{SO}_4</math> / <math>\text{HNO}_3</math> or (solid) <math>\text{CH}_3\text{NH}_3\text{Cl}</math> to lower the pH.</p>
(ii)	$\text{CH}_3\text{NH}_3^+ + \text{H}_2\text{O} \rightleftharpoons \text{CH}_3\text{NH}_2 + \text{H}_3\text{O}^+$ $K_a = \frac{[\text{CH}_3\text{NH}_2][\text{H}_3\text{O}^+]}{[\text{CH}_3\text{NH}_3^+]}$ $2.51 \times 10^{-11} = \frac{0.840 \times 10^{-12.1}}{[\text{CH}_3\text{NH}_3^+]}$ $[\text{CH}_3\text{NH}_3^+] = 0.0266 \text{ mol L}^{-1}$ $n(\text{CH}_3\text{NH}_3^+) = cv = 0.0266 \times 0.600 = 0.0159 \text{ mol}$ $m(\text{CH}_3\text{NH}_3\text{Cl}) = 0.0159 \times 67.5 = 1.08 \text{ g}$	<ul style="list-style-type: none"> <li>Correct process to calculate <math>[\text{CH}_3\text{NH}_3^+]</math>.</li> </ul>	<ul style="list-style-type: none"> <li>Correct process to calculate the mass of <math>\text{CH}_3\text{NH}_3\text{Cl}</math>, but minor error.</li> </ul>	
(iii)	<p>For a solution to function as a buffer solution, the pH of the solution needs to be equal to <math>\text{p}K_a \pm 1</math>. For this buffer solution, the pH would therefore need to fall within the range 9.6 – 11.6. Since the pH is 12.1, the solution will not function as a buffer.</p> <p>The pH of the solution needs to be decreased. This could be achieved by adding a strong acid, like HCl, until the pH falls within the range. Alternatively, solid <math>\text{CH}_3\text{NH}_3\text{Cl}</math> could be added.</p>	<ul style="list-style-type: none"> <li>Identifies why the solution cannot function as a buffer.</li> </ul> <p>OR</p> <p>Recognises the pH of the solution needs to decrease.</p>	<ul style="list-style-type: none"> <li>Explains why the solution cannot function as a buffer with reference to <math>\text{p}K_a</math> and the pH range.</li> </ul> <p>OR</p> <p>Explains how the pH could be decreased to the appropriate pH range by addition of an acid / <math>\text{H}_3\text{O}^+</math> ions.</p>	

(c)	<p>HBr is a strong acid and completely dissociates to produce a relatively high <math>[H_3O^+]</math>. As a result, HBr has a low pH.</p> $HBr + H_2O \rightarrow Br^- + H_3O^+$ <p><math>NH_4Cl</math> is an acidic salt. The <math>NH_4^+</math> is a weak acid and partially dissociates to produce a lower <math>[H_3O^+]</math> than HBr. As a result, <math>NH_4^+</math> has a higher pH than HBr.</p> $NH_4^+ + H_2O \rightleftharpoons NH_3 + H_3O^+$ <p><math>CH_3NH_2</math> is a weak base and partially dissociates to produce a higher <math>[OH^-]</math> than the other two solutions, and therefore the lowest <math>[H_3O^+]</math> of the three solutions. As a result, <math>CH_3NH_2</math> has the highest pH.</p> $CH_3NH_2 + H_2O \rightleftharpoons CH_3NH_3^+ + OH^-$	<ul style="list-style-type: none"> <li>Recognises HBr has the highest <math>[H_3O^+]</math> / <math>CH_3NH_2</math> has the lowest <math>[H_3O^+]</math>.</li> <li>Recognised HBr fully dissociates, but <math>NH_4^+</math> or <math>CH_3NH_2</math> only partially dissociates.</li> </ul>	<ul style="list-style-type: none"> <li>Explains the order for TWO of the solutions (OK to refer to only <math>OH^-</math> for <math>CH_3NH_2</math>).</li> </ul>	<ul style="list-style-type: none"> <li>Justifies the order in terms of degree of dissociation and <math>[H_3O^+]</math>, including at least THREE relevant equations.</li> </ul>

Q	Evidence	Achievement	Achievement with Merit	Achievement with Excellence
THREE (a)	<p>A suitable indicator would need to change colour at the equivalence point/over the vertical section of the curve. From the curve, the equivalence point occurs around pH 5.8/vertical section from around 4-8. Since methyl red has a <math>pK_a</math> of 5.1, it will change colour over a pH range of 4.1 – 6.1, so will change colour at the equivalence point/over the vertical section. Thymol blue will change colour over a pH range of 0.7 – 2.7, so it will be unsuitable since it will change colour <b>after</b> the equivalence point.</p>	<ul style="list-style-type: none"> <li>Recognises methyl red will change colour at the equivalence point since its <math>pK_a</math> is close to the equivalence point / falls in vertical section.</li> </ul> <p>OR</p> <p>Thymol blue will change colour after the equivalence point since its <math>pK_a</math> falls <b>after</b> the equivalence point / vertical section.</p>	<ul style="list-style-type: none"> <li>Explains the suitability of each indicator in terms of the pH range over which each indicator changes colour relative to the estimated equivalence point pH.</li> </ul>	
(b)(i)	$NH_4^+ + H_2O \rightleftharpoons NH_3 + H_3O^+$ $K_a = \frac{[NH_3][H_3O^+]}{[NH_4^+]}$ $5.75 \times 10^{-10} = \frac{[H_3O^+]^2}{\left(0.0139 \times \frac{25}{45}\right)}$ $[H_3O^+] = 2.11 \times 10^{-6} \text{ mol L}^{-1}$ $pH = -\log(2.11 \times 10^{-6})$ $= 5.68$	<ul style="list-style-type: none"> <li>Correct process to calculate pH of an acidic solution.</li> </ul>	<ul style="list-style-type: none"> <li>Calculates pH, but does not appropriately dilute the solution (pH will be 5.55 if does not dilute).</li> </ul>	<ul style="list-style-type: none"> <li>Correctly calculates pH at equivalence point, including 2–4 significant figures.</li> </ul>
(ii)	<p>The initial ammonia solution is weakly basic, so the <math>NH_3</math> only partially dissociates to produce a relatively low <math>[NH_4^+]</math> and <math>[OH^-]</math>:</p> $NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$ <p>Since [ions] is low, the solution is a poor conductor.</p> <p>After 20.0 mL of HCl has been added, the solution in the conical flask consists of an acidic salt that has completely dissociated to produce high <math>[NH_4^+]</math> ions and high <math>[Cl^-]</math> ions. Although a small proportion of the <math>NH_4^+</math> ions will dissociate, the solution still has a high [ions] and is therefore a good electrical conductor.</p> $NH_4Cl \rightarrow NH_4^+ + Cl^-$	<ul style="list-style-type: none"> <li>Recognises a solution requires ions to conduct electricity.</li> <li>Identifies <math>NH_3</math> as a poor conductor and <math>NH_4Cl</math> as a good conductor.</li> </ul> <p>OR</p> <p>Recognises electrical conductivity increases.</p>	<ul style="list-style-type: none"> <li>Links conductivity of ONE solution to the degree of dissociation and [ions] in solution.</li> </ul>	<p>AND</p> <p>Links conductivity of BOTH solutions to the degree of dissociation and [ions] in solution, including at least one supporting equation.</p>

(c)(i)	$n(\text{HCl}) = cv = 0.0174 \times 0.005 = 8.7 \times 10^{-5} \text{ mol}$ $c(\text{HCl}) = \frac{8.7 \times 10^{-5} \text{ mol}}{0.05 \text{ L}} = 1.74 \times 10^{-3} \text{ mol L}^{-1}$ $\text{pH} = -\log 1.74 \times 10^{-3}$ $= 2.76$	<ul style="list-style-type: none"> <li>Calculates the correct moles of HCl.</li> </ul> OR [HCl]	<ul style="list-style-type: none"> <li>Correct process for calculating pH, but minor error.</li> </ul> OR	<ul style="list-style-type: none"> <li>Correct pH of diluted HCl and explanation as to why the pH is higher than the original HCl solution.</li> </ul>
(ii)	The pH is higher because the volume of solution in which the HCl is contained is much larger / the HCl has been diluted. As a result, there is a decrease in $[\text{H}_3\text{O}^+]$ , so the pH is higher.	<ul style="list-style-type: none"> <li>Recognises the HCl has been diluted / there are less <math>\text{H}_3\text{O}^+</math> per unit volume.</li> </ul>	Links increase in pH of HCl to decrease in $[\text{H}_3\text{O}^+]$ due to dilution.
